Repeated measures ANOVA Repeated measures analysis of variance (rANOVA) is a commonly used statistical approach to repeated measure designs. [3] With such designs, the repeated-measure factor (the qualitative independent variable) is the within-subjects factor, while the dependent quantitative variable on which each participant is measured is the dependent variable.

The repeated measures ANOVA is a member of the ANOVA family. ANOVA is short for ANalysis Of VAriance. All ANOVAs compare one or more mean scores with each other; they are tests for the difference in mean scores. The repeated measures ANOVA compares means across one or more variables that are based on repeated observations.

Repeated measures ANOVA – not preferred since they require balanced and complete data sets, require normally distributed response variables and do not allow for the analysis of covariates that change over time. Data are in the form of one row per subject. If there is no control group, use a One-way repeated-measures ANOVA.

Repeated Measures ANOVA - Simple Introduction

An ANOVA with repeated measures is used to compare three or more group means where the participants are the same in each group. This usually occurs in two situations: (1) when participants are measured multiple times to see changes to an intervention; or (2) when participants are subjected to more than one condition/trial and

SPSS repeated measures ANOVA tests if the means of 3 or more metric variables are all equal in some population. If this is true and we inspect a sample from our population, the sample means may differ a little bit. Large sample differences, however, are unlikely; these suggest that the population means weren't equal after all. The simplest repeated measures ANOVA involves 3 outcome variables, all measured on 1 group of cases (often people).
